

Three databases. **Three jobs.**

POSTGRESQL

transactional and relational state

BIGQUERY

the on-chain analytics workload

REDIS

sub-ms answers to repeated reads

One DB doing all three is **the expensive shortcut.**

THE SHORTCUT

a common seed-stage bet

THE COST

the exact latency and cost problems this stack avoids

Purpose-built, each queried for **what it's good at.**

THE RESULT

<200ms p99 and 99.9% uptime together

THE POINT

three purpose-built systems, not accumulated complexity
